The compounds of Formula I and Formula III of the present invention are useful for the treatment of various memory dysfunctions characterized by a decreased cholinergic function such as Alzheimer's disease. Compounds of this invention also inhibit monoamine oxidase and/or act at central α_2 -adrenergic receptors and hence are useful as antidepressants.

The activity to alleviate such memory dysfunctions is manifested by the ability of these compounds to inhibit the enzyme acetylcholinesterase and thereby increase acetylcholine levels in the brain.

Cholinesterase Inhibition Assay

Cholinesterases are found throughout the body, both in the brain and in serum. However, only brain acetylcholinesterase (AChE) distribution is correlated with central cholinergic innervation. This same innervation is suggested to be weakened in Alzheimer patients. We have determined *in vitro* inhibition of acetylcholinesterase activity in rat striatum.

In Vitro Inhibition of Acetylcholinesterase Activity in Rat Striatum

Acetylcholinesterase (AChE), which is sometimes called true or specific cholinesterase, is found in nerve cells, skeletal muscle, smooth muscle, various glands and red blood cells. AChE may be distinguished from other cholinesterases by substrate and inhibitor specificities and by regional distribution. Its distribution in brain roughly correlates with cholinergic innervation and subfractionation shows the highest level in nerve terminals.

It is generally accepted that the physiological role of AChE is the rapid hydrolysis and inactivation of acetylcholine.

Inhibitors of AChE show marked cholinomimetic effects in cholinergically-innervated effector organs and have been used therapeutically in the treatment of glaucoma, myasthenia gravis and paralytic ileus. However, recent studies have suggested that AChE inhibitors may also be beneficial in the treatment of Alzheimer's disease.

The method described below was used in this invention for assaying cholinesterase activity. This is a modification of the method of Ellman et al., *Biochem. Pharmacol.* 7, 88 (1961).

Procedure:

- (b) 13.40 g $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$ /100 ml distilled H_2O
- (c) add (a) to (b) until pH reaches 7.2
- (d) Dilute 1:10

2. Substrate in buffer

- (a) 198 mg acetylthiocholine chloride (10 mM)
- (b) q.s. to 100 ml with 0.05 M phosphate buffer,

pH 7.2 (reagent 1)

3. DTNB in buffer

- (a) 19.8 mg 5,5-dithiobisnitrobenzoic acid (DTNB) (0.5 mM)

4. A 2 mM stock solution of the test drug is made up in a suitable solvent and q.s. to volume with 0.5 mM DTNB (reagent 3). Drugs are serially diluted (1:10) such that the final concentration (in cuvette) is 10^{-4}M and screened for activity. If active, IC_{50} values are determined from the inhibitory activity of subsequent concentrations.

B. Tissue Preparation -

A 25 microliter aliquot of the homogenate is added to 1.0 milliter vehicle or various concentrations of the test drug and preincubated for 10 minutes at 37°C .

C. Assay -

Enzyme activity is measured with the Beckman DU-50 spectrophotometer. This method can be used for IC_{50} determinations and for measuring kinetic constants.

Instrument Settings

Kinetics Soft-Pac Module #598273 (10) Program #6 Kindata:

Source - Vis
Wavelength - 412 nm
Sipper - none
Cuvettes - 2 ml cuvettes using auto 6-sampler
Blank - 1 for each substrate concentration
Interval time - 15 seconds (15 or 30 seconds for kinetics)
Total time - 5 minutes (5 or 10 minutes for kinetics)
Plot - yes

Reagents are added to the blank and sample cuvettes as follows:

<u>Blank:</u>	0.8 ml Phosphate Buffer/DTNB 0.8 ml Buffer/Substrate

$$\% \text{ Inhibition} = \frac{\text{slope control} - \text{slope drug}}{\text{slope control}} \times 100$$

IC₅₀ values are calculated from log-probit analysis.

Results of this assay for some of the compounds of this invention and physostigmine (reference compound) are presented in Table 1.

This utility is further demonstrated by the ability of these compounds to restore cholinergically deficient memory in the Dark Avoidance Assay described below.

Dark Avoidance Assay

In this assay mice are tested for their ability to remember an unpleasant stimulus for a period of 24 hours. A mouse is placed in a chamber that contains a dark compartment; a strong incandescent light drives it to the dark compartment, where an electric shock is administered through metal plates on the floor. The animal is removed from the testing apparatus and tested again, 24 hours later, for the ability to remember the electric shock.

If scopolamine, an anticholinergic that is known to cause memory impairment, is administered before an animal's initial exposure to the test chamber, the animal re-enters the dark compartment shortly after being placed in the test

chamber 24 hours later. This effect of scopolamine is blocked by an active test compound, resulting in a greater interval before re-entry into the dark compartment.

The results for an active compound are expressed as the percent of a group of animals in which the effect of scopolamine is blocked, as manifested by an increased interval between being placed in the test chamber and re-entering the dark compartment.

Results of this assay for some of the compounds of this invention and those for tacrine and pilocarpine (reference compounds) are presented in Table 2.

TABLE 2

Compound	Dose (mg/kg of body weight, s.c)	% of Animals with Scopolamine Induced Memory Deficit Reversal

	2.5	33%
Tacrine	0.63	13%
Pilocarpine	5.0	13%

The utility is further demonstrated by the ability of these compounds to inhibit the enzyme monoamine oxidase, increase the brain levels of biogenic amine(s), and act as antidepressants.

Inhibition of Type A and Type B Monoamine Oxidase Activity in Rat Brain Synaptosomes

Purpose

To determine the selective inhibition of the two forms of monoamine oxidase (MAO).

Introduction

The metabolic deamination of amines has been known for described two forms of monoamine oxidase, which are called "type A" and "type B". The existence of the two forms is based on different substrate and inhibitor specificities. Serotonin (5HT) and norepinephrine (NE) are substrates for type A MAO, β -phenethylamine (PEA) and benzylamine are substrates for type B MAO, while dopamine (DA) and tyramine are substrates for both types. Clorgyline is a selective inhibitor of the type A enzyme, deprenyl and pargyline are selective inhibitors of the type B enzyme and tranlycypromine and iproniazid are nonselective inhibitors (2). It is recognized that MAO inhibitors have antidepressant properties.

Although various methods for measuring MAO activity are available, the described method involves the extraction of the radiolabeled deaminated metabolites of [^3H]-5HT or [^{14}C]- β -phenethylamine. This procedure allows MAO-A and MAO-B activities to be measured either simultaneously or individually (3).

21.4 g sucrose, q.s. to 250 ml with 0.05 M PO_4 buffer

3. Substrate for MAO-A:

a. Serotonin creatine SO_4 (5HT) is obtained from Sigma Chemical Company. A 5 mM stock solution is made

up in 0.01 N HCl. This is used to dilute the specific activity of the [^3H]-5HT.

b. [^3H]-5-Hydroxytryptamine binoxalate (20-30 Ci/mmol) is obtained from New England Nuclear.

c. Add 12 μl of [^3H]-5HT to 2 ml of the 5 mM 5HT solution. (Final amine concentration in the assay is 200 μM ; see below.)

4. Substrate for MAO-B

a. β -phenethylamine (PEA) is obtained from Sigma Chemical Company. A 5 mM stock solution is made up in 0.01 N HCl. This is used to dilute the specific activity of the [^{14}C]-PEA.

b. β -[ethyl- ^{14}C]-phenethylamine hydrochloride (40-50 mCi/mmol) is obtained from New England Nuclear.

c. Add 12 μl of [^{14}C]-PEA to 2 ml of the 5 mM PEA solution. (Final amine concentration in the assay is 200 μM ; see below.)

5. Equal amounts of MAO-A (5HT) and MAO-B (PEA) substrates are combined for simultaneously testing both MAO types, i.e. mixed stock solution of 2.5 mM 5HT and 2.5 mM PEA, 40 μl of this mixed solution gives a 200 μM final concentration of each amine in the assay. When testing only one MAO type, the individual 5 mM stock solutions must be diluted 1:1 with distilled water prior to adding 40 μl to the incubation mixture; i.e., same 200 μM final amine concentration.

B. Tissue Preparation

Male Wistar rats weighting 15-250 grams were sacrificed and the brains rapidly removed. Whole brain minus cerebellum was homogenized in 30 volumes of ice-cold, phosphate-buffered 0.25 M sucrose, using a Potter-Elvehjem homogenizer. The homogenate was centrifuged at 1000 g for 10 minutes and the supernatant (S_1) decanted and recentrifuged at 18,000 g for 20 minutes. The resulting pellet (P_2) was resuspended in fresh 0.25 M sucrose and served as the tissue source for mitochondrial MAO.

C. Assay

10 μl 0.5 M PO_4 buffer, pH 7.4

50 μl H_2O or appropriate drug concentration

400 μl Tissue suspension

Tubes are preincubated for 15 minutes at 37°C and the assay is started by adding 40 μl of combined substrate ([^3H]-5HT and [^{14}C]-PEA) at 15 second intervals. The tubes are incubated for 30 minutes at 37°C and the reaction stopped by the addition of 0.3 ml 2N HCl. Tissue blank values are determined by adding the acid before the radioactive substrate. The oxidative products of the reaction are extracted with ethyl acetate/toluene (1:1). 5 ml of this mixture is added to the tubes. The resultant mixture is vortexed for 15 seconds to extract the deaminated metabolites into the organic phase and the latter is allowed to separate from the aqueous phase. The tubes are placed in acetone/dry ice bath to freeze the aqueous layer. When this layer is frozen, the top organic layer is poured into a scintillation vial. 10 ml of Liquiscint is added and the samples are counted using window settings for ^{14}C in one channel and ^3H in the second channel. IC_{50} values are determined by log-probit analysis.

The present inventors have also conducted Clonidine Binding Assay described below in order to ascertain the interaction of the compounds of this invention with α_2 -receptors.

³H-Clonidine Binding: α_2 -Receptor

Introduction:

A number of antidepressants have been shown to enhance neuronal release of norepinephrine by a presumed presynaptic α_2 -receptor blockade and this property may be of significance with respect to the mechanism of action of these compounds. See references 1, 2 and 3 cited below. The interaction of a compound with central α_2 -receptors is assessed in the ³H-clonidine binding assay.

Procedure

A. Reagents

1.

- a. 57.2 g Tris HCl
16.2 g Tris Base - q.s. to 1 liter (0.5 M Tris buffer, pH 7.7)
- b. Make a 1:10 dilution in distilled H₂O (0.05 M Tris buffer, pH 7.7)

2. Tris buffer containing physiological ions

a. Stock Buffer

NaCl	7.014 g
KCl	0.372 g
CaCl ₂	0.222 g - q.s. to 100 ml in 0.5 M Tris buffer
MgCl ₂	0.204 g

b. Dilute 1:10 in distilled H₂O. This yields 0.05 M Tris HCl, pH 7.7; containing NaCl (120 mM), KCl (5mM), CaCl₂ (2 mM) and MgCl₂ (1 mM)

3. [4-³H]-Clonidine hydrochloride (20-30 Ci/mmol) is obtained from New England Nuclear. For IC₅₀

determinations: ^3H -Clonidine is made up to a concentration of 120 nM and 50 μl added to each tube (yields a final concentration of 3 nM in the 2 ml volume assay).

4. Clonidine-HCl is obtained from Boehringer Ingelheim. A stock solution of 0.1 mM clonidine is made up to determine nonspecific binding. This yields a final concentration of 1 μM in the assay (20 μl to 2 ml).

5. Test compounds. For most assays, a 1 mM stock solution is made up in a suitable solvent and serially diluted, such that the final concentration in the assay ranges from 10^{-6} to 10^{-8}M . Seven concentrations are used for each assay and higher or lower concentrations may be used, depending on the potency of the drug.

B. Tissue Preparation

Male Wistar rats are sacrificed by decapitation and the cortical tissue rapidly dissected. The tissue is homogenized in 50 volumes of 0.05 M Tris buffer, pH 7.7 (buffer 1b) with the Brinkman Polytron, then centrifuged at 40,000 g for 15 minutes. The supernatant is discarded and the pellet re-homogenized in the original volume of 0.05 M Tris buffer, pH 7.7 and re-centrifuged as before. The supernate is discarded and the final pellet re-homogenized in 50 volumes of buffer 2b. This tissue suspension is then stored on ice. The final tissue concentration is 10 mg/ml. Specific binding is 1% of the total added ligand and 80% of total bound ligand.

C. Assay

100 μl	0.5 M Tris-physiological salts, pH 7.7 (buffer 2a)
830 μl	H_2O
20 μl	Vehicle (for total binding) or 0.1 mM clonidine (for nonspecific binding) or appropriate drug concentration
50 μl	^3H -clonidine stock
1000 μl	tissue suspension

Tissue homogenates are incubated for 20 minutes at 25°C with 3 nM ^3H -clonidine and varying drug concentrations, and thereafter immediately filtered under reduced pressure on Whatman GF/B filters. The filters are washed with three five ml volumes of ice-cold 0.05 M Tris buffer, pH 7.7, and thereafter transferred to scintillation vials. Ten ml of Liquescent counting solution is added to each sample which is then counted by liquid scintillation spectroscopy. Specific clonidine binding is defined as the difference between total bound and that performed using log-probit analysis. The percent inhibition at each drug concentration is the mean of triplicate determinations.

Effective quantities of the compounds of the invention may be administered to a patient by any of the various methods, for example, orally as in capsule or tablets, parenterally in the form of sterile solutions or suspensions, and

in some cases intravenously in the form of sterile solutions. The free base final products, while effective themselves, may be formulated and administered in the form of their pharmaceutically acceptable acid addition salts for purposes of stability, convenience of crystallization, increased solubility and the like.

Acids useful for preparing the pharmaceutically acceptable acid addition salts of the invention include inorganic acids such as hydrochloric, hydrobromic, sulfuric, nitric, phosphoric and perchloric acids, as well as organic acids such as tartaric, citric, acetic, succinic, maleic, fumaric 2-naphthalenesulfonic and oxalic acids.

The active compounds of the present invention may be orally administered, for example, with an inert diluent or with an edible carrier, or they may be enclosed in gelatin capsules, or they may be compressed into tablets. For the purpose of oral therapeutic administration, the active compounds of the invention may be incorporated with excipients and used in the form of tablets, troches, capsules, elixirs, suspensions, syrups, wafers, chewing gum and the like. These preparations should contain at least 0.5% of active compounds, but may be varied depending upon the particular form and may conveniently be between 4% to about 70% of the weight of the unit. The amount of active compound in such compositions is such that a suitable dosage will be obtained. Preferred compositions and preparations according to the present invention are prepared so that an oral dosage unit form contains between 1.0 - 300 milligrams of active compound.

The tablets, pills, capsules, troches and the like may also contain the following ingredients: a binder such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, comstarch and the like; a lubricant such as magnesium stearate or Sterotex; a glidant such as colloidal silicon dioxide; and a sweetening agent such as sucrose or saccharin may be added or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring. When the dosage unit form is a capsule, it may contain, in addition to materials of the above type, a liquid carrier such as a fatty oil. Other dosage unit forms may contain other various materials which modify the physical form of the dosage unit, for example, as coatings. Thus, tablets or pills may be coated with sugar, shellac, or other enteric coating agents. A syrup may contain, in addition to the active compounds, sucrose as a sweetening agent and certain preservatives, dyes, coloring and flavors. Materials used in preparing these various compositions should be pharmaceutically pure and non-toxic in the amounts used.

For the purpose of parenteral therapeutic administration, the active compounds of the invention may be incorporated into a solution or suspension. These preparations should contain at least 0.1% of active compound, but may be varied between 0.5 and about 30% of the weight thereof. The amount of active compound in such compositions is such that a suitable dosage will be obtained. Preferred compositions and preparations according to the present inventions are prepared so that a parenteral dosage unit contains between 0.5 to 100 milligrams of active compound.

The solutions or suspensions may also include the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; antibacterial agents such as benzyl alcohol or methyl parabens; antioxidants such as ascorbic acid or sodium bisulfite; chelating agents such as ethylenediaminetetraacetic acid; buffers such as acetates, citrates or phosphates and agents for the adjustment of tonicity such as sodium chloride or dextrose. The parenteral preparation can be enclosed in disposable syringes or multiple dose vials made of glass or plastic.
